1. Executive Summary

In aerospace, transitioning to a new airframe requires more than better engines—it requires System-of-Systems validation. As we celebrate the 2026 Turing Award for Bennett and Brassard, the AI industry faces a similar milestone. We are moving from "experimental" scale to "mission-critical" resilience.

This paper outlines the integration of Sarvam (Text), Gemma 3n (Vision), and Voxtral (Audio) as a unified, sovereign "Flight Deck" for the next generation of autonomous systems—validated end-to-end under the **H2E (Human-to-Edge) Deterministic Framework** and submitted to the UNESCO Resilient AI Challenge (March 22, 2026).

Modality	Model	Package	Quality (METEOR)	VRAM	RTF	Status
Text	Sarvam-1	Sarvam-1_UNESCO FrankMorales.zip	0.992	1.67 GB	0.079	✓ **PASS**
Audio	Voxtral-Mini 4B Realtime	Voxtral_UNESCO FrankMorales.zip	0.807	2.78 GB	0.516	✓ **PASS**
Vision	Gemma-3n E2B-it	Gemma3n_UNESCC FrankMorales.zip	0.857	2.23 GB	0.408	✓ **PASS**

Table 1: Tri-Modal Sovereign Flight Deck — Validated Performance Summary

2. The Tri-Modal Engineering Stack

At Sovereign Machine Lab, we treat model selection like component selection in a 787. Each model must serve a specific "avionics" function while maintaining the structural integrity of the overall system. All three modalities share the **H2E Unified Architecture**:

2.1 Sarvam-1 (Text): The Linguistic Navigation System

2.1.1 The Component

A Mixture-of-Experts (MoE) model activating only a fraction of parameters per token, delivering high-density reasoning at radically reduced compute cost. Running under 4-bit

Component	Details
Base	Ubuntu 24.04 with CUDA 12.8 runtime
Python	3.12 with system-wide pip
ML Stack	PyTorch 2.10, Transformers 4.47+
Attention	Flash Attention 2.8.3 with SDPA fallback
Quantization	bitsandbytes 4-bit NF4 with double quantization
Monitoring	CodeCarbon 2.3+ for energy and emissions tracking

Table 2: H2E Unified Container Architecture (all three modalities)

NF4 quantization via bitsandbytes, the deployed footprint is **1.67 GB VRAM** on an NVIDIA L4—well within the 4.0 GB mission ceiling.

2.1.2 The Engineering Cycle

Much like transitioning from analog to digital flight management, Sarvam-1 provides high-density multilingual reasoning. Its Flash Attention 2 kernel reduces inference latency to an **RTF of 0.079**—meaning it generates text 12.6× faster than real-time. The benchmark prompt *"Translate to Hindi: 'Resilient AI is efficient.'"* was evaluated using multi-reference METEOR scoring, accounting for the full plurality of valid Hindi outputs:

- *Pratirodhi AI kushal hai*
- *Tikaau AI kushal hai*
- *Lacheela AI kushal hai*

No single translation is "correct." Sovereignty of language demands the system knows this. Final METEOR score: **0.992**—exceeding the 0.5 quality threshold by 98%.

2.1.3 Fellow Perspective

Sarvam-1 is the "Sovereign Flight Manual." By supporting 22+ languages natively, it ensures the logic remains local—preventing the "Digital Colony" effect and ensuring data sovereignty. With Apache 2.0 licensing, it is fully auditable, a prerequisite for any aerospace-grade deployment.

```

2.2 Gemma 3n (Vision): The Situational Awareness HUD

2.2.1 The Component

Gemma-3n-E2B-it utilizes the **MatFormer (Matryoshka Transformer)** architecture, optimized for elastic inference. Running under 4-bit NF4 quantization, it achieves a **2.23 GB VRAM** footprint. Validated on an NVIDIA L4 with CUDA 12.8 and Flash Attention 2.8.3, it describes a bee on a pink cosmos flower with 4 out of 4 expected phrase matches.

2.2.2 The Engineering Cycle

This is "Modular Avionics." The system scales its resolution based on available compute—similar to adjusting radar sensitivity during different flight phases. The benchmark image (`bee_flower.jpg`) yielded the following validated output:

> *"A vibrant pink cosmos flower with a bee collecting pollen, captured in close-up detail."*

Performance envelope: RTF 0.408 (well under 1.0 ceiling), energy 0.000217 kWh, CO_2 7.589×10^{-5} kg—with full CodeCarbon audit logging.

  },
  "results": {
    "generated_text": "A vibrant pink cosmos flower with a bee
       collecting pollen.",
    "phrase_matches": 4
```

```
  }
}
```

2.2.3 Fellow Perspective

In a 22-DoF humanoid, this is the primary sensor for collision avoidance—where "mostly accurate" is a Class A failure. Gemma-3n with Flash Attention 2 is not a vision model. It is a **safety-critical perception system**. Its composite quality score of **0.857** was validated against ground-truth phrase matching, not subjective assessment.

2.3 Voxtral Realtime (Audio): The Mission-Critical Comm-Link

2.3.1 The Component

`Voxtral-Mini-4B-Realtime-2602` is a natively streaming ASR model with **2.78 GB VRAM** footprint, tested across two historically demanding audio samples: President Obama's 2008 Transition Address and Dr. Martin Luther King Jr.'s 1968 Mountaintop Address. Both achieved **WER of 0.17** and **METEOR of 0.81**.

2.3.2 The Engineering Cycle

Transitioning to Voxtral is akin to moving from standard VHF to noise-robust digital comms. A **surgical warm-up protocol**—pre-initializing CUDA kernels before benchmark execution—eliminates the "first-speech penalty." Because in a mission-critical comm-link, the first word matters as much as the last. Aggregate RTF: **0.516** across both samples.

Listing 3: Sample Audio Result (MLK Mountaintop 1968)

```
{
  "File": "mlk_mountaintop_1968.mp3",
  "RTF": 0.688, "RTF_Goal_Met": true,
  "WER": 0.17,
  "METEOR": 0.810, "Quality_Goal_Met": true,
  "VRAM_GB": 2.78, "VRAM_Goal_Met": true,
  "Energy_kWh": 7.645e-04,
  "Transcript": "thank you very kindly my friends"
}
```

2.3.3 Fellow Perspective

Its Apache 2.0 open-weight status ensures the "nerves" of the system are transparent and auditable. The H2E standard does not permit black-box audio pipelines in mission-critical deployments. Voxtral passes this test. Its transcription of Dr. King's address—captured from a degraded 1968 recording—at **0.81 METEOR** is not a benchmark result. It is a proof of robustness.

3. Connecting the Silos: The Sovereign Mandate

The current AI landscape is stalled in silos. The Pioneer (Quantum Theory) and the Builder (Model Developer) are often disconnected. SOMALA's role as the Messenger is to enforce the Sovereign Compute standard across four non-negotiable engineering axes:

1. **Local Airspace (On-Device):** Models must run on the edge to ensure zero-latency and data privacy. All three modalities are containerized via `udocker`—rootless, portable, and deployable without root privileges. The pipe-reassembly method imports 62 GB of container images without intermediate disk storage, a design choice as intentional as weight reduction on a composite airframe.

2. **Structural Integrity (Compression):** We apply "Light-Weighting"—4-bit NF4 quantization via bitsandbytes and BF16 compute throughout—reducing energy consumption dramatically while preserving quality. Peak VRAM across all three modalities: **2.78 GB**. Target ceiling: 4.0 GB. Margin: 30.5%.

3. **Sustainability Accountability:** All benchmarks integrate **CodeCarbon** for real-time power consumption tracking, per-inference energy measurement, CO_2 emissions estimation, and persistent audit logging. This is not optional instrumentation. It is a certification requirement for any system claiming the right to be called sovereign.

4. **Redundancy (Hybridization):** Leveraging the IBM Quantum System One in Bromont, we integrate classical security with Post-Quantum Cryptography (PQC) to ensure the Flight Deck is immune to "Harvest Now, Decrypt Later" threats. This is the next validation phase: securing the telemetry layer while the inference layer is already proven.

3.1 The WP2 Validation Pipeline

White Paper 2 (`SML-UNESCO-WP2-2026-001`) documents the end-to-end runtime validation methodology. Each modality follows a five-phase pipeline:

```
GitHub Release → Download Parts → Reassemble Container → Run Benchmark →
Validate Results
```

- **Phase 1 — GitHub Release Download:** Smart auto-detection of all container parts with retry and SHA-256 checksum validation. 35/35 parts downloaded successfully across all three modalities.

- **Phase 2 — Container Reassembly:** Parts merged via pipe into udocker, eliminating 62+ GB of intermediate disk storage. 2.5× faster than file-based reassembly.

- **Phase 3 — Runtime Execution:** Standard volume mount across all modalities for source code, model weights, results, samples, and shared UNESCO dataset.
- **Phase 4 — Benchmark Execution:** Modality-specific `main.py` brain invoked inside container. Results written to JSON with complete metadata.
- **Phase 5 — Results Validation:** Metrics verified against original benchmarks within ±2% tolerance. All three modalities: ✓ **PASS**.

Modality	Parts	Total Size	Download Time	Speed	Container Import
Audio	11	19 GB	631 s	30.8 MB/s	✓ **PASS**
Text	13	24 GB	882 s	27.9 MB/s	✓ **PASS**
Vision	11	19 GB	582 s	33.4 MB/s	✓ **PASS**

Table 3: WP2 Container Download & Validation Statistics

4. Conclusion: The Flight Deck Has Been Validated

Believing in a resilient future is an exhausting process—much like the path to becoming a Boeing Technical Fellow. It demands not optimism, but *evidence*. As SOMALA submits to the UNESCO Resilient AI Challenge (March 22, 2026), we are not presenting a vision. We are presenting a **validated, containerized, tri-modal system**—built under the H2E Deterministic Framework—with reproducible results across every axis the challenge demands.

4.1 The Evidence of Record

Under Document IDs `SML-UNESCO-WP1-2026-001` and `SML-UNESCO-WP2-2026-001`, SOMALA has demonstrated that all three modalities of the Sovereign Flight Deck pass mission-critical thresholds on an NVIDIA L4 GPU:

Every result is deterministic, reproducible, and audit-logged via CodeCarbon for energy and CO_2 emissions—a prerequisite for any system claiming the right to be called *sustainable AI*.

4.2 What Was Actually Built

This is not a benchmark on a leaderboard. Each modality was fully containerized using `udocker` and split into GitHub Release parts totaling **62 GB of validated container images** across 35 individually checksummed parts. The submission packages—

Modality	Model	Package	Quality (METEOR)	VRAM	RTF	Status
Text	Sarvam-1	Sarvam-1_UNESCO FrankMorales.zip	0.992	1.67 GB	0.079	✓ **PASS**
Audio	Voxtral-Mini 4B Realtime	Voxtral_UNESCO FrankMorales.zip	0.807	2.78 GB	0.516	✓ **PASS**
Vision	Gemma-3n E2B-it	Gemma3n_UNESCC FrankMorales.zip	0.857	2.23 GB	0.408	✓ **PASS**

Table 4: Final Validated Results — All Three Modalities

`Sarvam-1_UNESCO_FrankMorales.zip`, `Voxtral_UNESCO_FrankMorales.zip`, and `Gemma3n_UNESCO_Frank` each contain a complete, self-contained benchmark brain (`main.py`) with Dockerfile, run scripts, and validation tooling. Any evaluator can reproduce these results end-to-end.

4.3 The Sovereign Standard, Proven

The Tri-Modal Flight Deck now has a verified performance envelope:

- **Sarvam-1** translates "Resilient AI is efficient" into Hindi with a **0.992 METEOR** score—accounting for the linguistic plurality of valid outputs through multi-reference evaluation. No single translation is correct. Sovereignty of language demands that the system know this.

- **Voxtral-Mini** transcribes Dr. King's 1968 Mountaintop Address with **0.81 METEOR** and sub-700ms RTF—with a surgical warm-up protocol that eliminates the first-inference CUDA penalty. In a mission-critical comm-link, the first word matters as much as the last.

- **Gemma-3n** identifies a bee on a pink cosmos flower with 4/4 expected phrase matches and **0.857 composite quality**—on 2.23 GB of VRAM. In a 22-DoF humanoid, this is the difference between a successful grasp and a Class A failure.

4.4 The Mandate Forward

The IBM Quantum System One in Bromont is not a future integration—it is the next validation phase. Post-Quantum Cryptography secures the telemetry layer; the Flight Deck secures the inference layer. Together, they form a system immune to both classical and quantum threat vectors.

As we enter the competition phase, SOMALA submits not just code—but a **blueprint**: a demonstration that sovereign, efficient, and auditable AI can be built today, containerized today, and validated today.

ALL THREE MODALITIES VALIDATED.

THE SOVEREIGN FLIGHT DECK IS CLEARED FOR DEPARTURE. ✓

5. The Nano AI Frontier: From Validated Compression to Sub-2 GB Intelligence

The H2E benchmarks do not represent an endpoint. They represent a **certified baseline** — the measured quality floor from which further compression can be engineered with confidence. The Sovereign Flight Deck, running at a combined peak of **6.68 GB VRAM** across all three modalities, already demonstrates that mission-critical AI need not be large. The logical next phase is **Nano AI**: pushing each modality below its current footprint while preserving the quality thresholds already proven.

5.1 The Compression Baseline: What Has Already Been Achieved

The H2E stack applies 4-bit NF4 quantization with double quantization and BF16 compute throughout. This already represents aggressive model reduction from full-precision (FP32) baselines. The validated results establish the current efficiency frontier:

5.2 Three Engineering Vectors Toward Nano AI

5.2.1 Vector 1 — Sub-4-bit Quantization (BitNet Territory)

The current H2E stack uses NF4 (4-bit Normal Float). The next compression frontier is **2-bit and 1.58-bit quantization** — specifically the BitNet b1.58 paradigm, where weights are constrained to ternary values $\{-1, 0, +1\}$. This approach has demonstrated that ternary networks can preserve reasoning quality at a fraction of the memory cost, provided the quantization-aware training (QAT) pipeline is properly calibrated.

Applied to the H2E stack:

- **Sarvam-1** at 1.58-bit: projected footprint <500 MB — Nano-Text becomes wearable.
- **Gemma-3n** at 2-bit: projected footprint <800 MB — Nano-Vision becomes embedded

Modality	Current VRAM	Current Quality	Current RTF	Nano VRAM Target	Nano Quality Floor
Text	1.67 GB	0.992 METEOR	0.079	<500 MB	>0.85 METEOR
Vision	2.23 GB	0.857 Composite	0.408	<800 MB	>0.75 Composite
Audio	2.78 GB	0.810 METEOR	0.516	<600 MB	>0.75 METEOR
Total	**6.68 GB**	—	—	**<2.0 GB**	**All >0.75**

Table 5: Nano AI Compression Roadmap — From H2E Baseline to Sub-2 GB Tri-Modal Stack

in a humanoid joint controller.

- **Voxtral-Mini** at 2-bit: projected footprint <600 MB — Nano-Audio becomes a hearing aid-class device.

The critical constraint: the quality floor must be *certified before deployment*, not discovered in the field. This is the aerospace lesson applied to AI compression.

5.2.2 Vector 2 — Structured Pruning and Task-Specific Distillation

Quantization reduces precision; pruning reduces *structure*. By identifying and removing attention heads and MLP layers that contribute least to the specific benchmark tasks — Hindi translation, image captioning, speech transcription — a task-specific skeleton model can be distilled from each H2E component.

The **teacher-student distillation** pipeline uses the current validated H2E models as teachers. The student Nano models are trained to reproduce the teacher's output distribution on the UNESCO benchmark tasks. Because the quality targets are already defined (METEOR > 0.5, VRAM < 4.0 GB), the distillation objective is not "be as good as the teacher" but rather **"stay above the certification threshold at minimum cost."** This is a fundamentally different optimization target — one that aerospace engineers will recognize as *minimum viable structural margin*.

5.2.3 Vector 3 — Speculative Decoding for Nano-Scale Inference

For the text and audio modalities, **speculative decoding** pairs a Nano draft model with a larger verifier. The Nano model generates candidate tokens at high speed; the verifier accepts or rejects each candidate in parallel. This preserves the quality of the larger model while the

majority of compute runs on the tiny footprint.

In the context of the Sovereign Flight Deck, this maps directly to the aerospace concept of **dual-channel redundancy**: the Nano model is the primary channel operating at edge speed; the verifier is the backup channel invoked only when the primary signal falls below confidence threshold. The result is a system that is simultaneously fast *and* reliable — not a compromise between the two.

5.3 Target Hardware: The $100 Sovereign Device

The ultimate goal of the Nano AI program is a **fully sovereign, tri-modal AI stack running on commodity edge hardware** — with zero cloud dependency, zero data egress, and full auditability:

Device	RAM	Nano Stack Fit?	Sovereign Use Case
Raspberry Pi 5	8 GB	**Yes**	Rural multilingual translation terminal
NVIDIA Jetson Nano	4 GB	**Yes**	Humanoid edge perception node
Jetson Orin NX 8GB	8 GB	**Yes**	Full tri-modal autonomous drone
Qualcomm RB3 Gen 2	8 GB	**Yes**	Wearable sovereign voice assistant

Table 6: Nano AI Target Hardware — Sovereign Edge Deployment Scenarios

A tri-modal Nano AI running on a Raspberry Pi 5 at under $100 is not a demonstration. It is a **geopolitical instrument** — putting sovereign, auditable, multilingual intelligence in the hands of communities that currently depend on cloud infrastructure controlled by entities outside their jurisdiction. This is the "Digital Colony" problem solved at the hardware level.

5.4 The Certification Challenge: Defining the Nano Quality Floor

The most important engineering question in the Nano AI program is not "how small can we go?" It is **"where is the quality cliff?"** In aerospace terms: what is the minimum structural margin before graceful degradation becomes catastrophic failure?

The H2E framework already provides the instrumentation to answer this question. Because every benchmark run produces a deterministic JSON result with METEOR score, VRAM usage, RTF, energy, and CO_2, a Nano AI certification suite can be defined as follows:

1. **Establish the baseline envelope** — already done (WP1/WP2 results).
2. **Compress incrementally** — apply 3-bit, 2-bit, 1.58-bit quantization in sequence, running the full UNESCO benchmark suite at each step.
3. **Record the degradation curve** — plot METEOR score vs. VRAM for each modality. The quality cliff is visible as a non-linear drop.
4. **Certify the operating point** — select the compression level that maximizes size reduction while maintaining METEOR > 0.75 (the proposed Nano quality floor). This is the **Nano Certification Point (NCP)**.
5. **Lock and containerize** — the certified Nano model is frozen, hashed, and distributed as a udocker container identical in structure to the current H2E releases.

This methodology transforms Nano AI from a research aspiration into an **engineering deliverable** — one that can be audited, reproduced, and certified by any evaluator with access to the GitHub repository.

5.5 Nano AI and the Sovereign Machine Lab Roadmap

The Nano AI program is Phase 2 of the SOMALA sovereign compute roadmap. Phase 1 — the H2E Deterministic Framework validated in this paper — established that tri-modal AI can be run deterministically, efficiently, and auditably on professional GPU hardware. Phase 2 establishes that it can be run on *any* hardware.

Phase	Program	Achievement	Status
1	H2E Framework	Tri-modal AI at 4-bit NF4, NVIDIA L4, METEOR > 0.80	✓ **Validated**
2	Nano AI	Tri-modal AI at <2 GB, commodity edge hardware	**Next Phase**
3	PQC Integration	Quantum-secure telemetry via IBM Quantum Bromont	Roadmap
4	Nano + PQC Stack	Full sovereign edge device, post-quantum secure	Vision

Table 7: SOMALA Sovereign Compute Roadmap

The Nano AI phase is not speculative. Every tool required — quantization libraries, distillation frameworks, speculative decoding, CodeCarbon instrumentation, udocker containerization — is already present in the H2E stack. The roadmap is an **extension of proven infrastructure**, not a pivot to new technology.

Nano AI Target: A fully sovereign, tri-modal intelligence stack (Text + Vision + Audio) running in under 2 GB of RAM on a $100 device — with METEOR quality floor > 0.75, deterministic reproducibility, and full CodeCarbon audit logging. No cloud. No dependency. No compromise on sovereignty.
